

How K was chosen — the spline df each cell selected by BIC on its own reduced model

fill and number = the retained K over the grid K = 1..20 · sparkline = that cell's own BIC-vs-K curve, red dot = its minimum

'edge' = the minimum sits on a grid endpoint — BIC reported the edge rather than turning · 'n/20 conv' = the other K did not converge

'N var/M sh' = the random part asks for N variances from M shoulders, so K is NOT identifiable: it describes the flexibility the optimiser bore, not the trajectory
